

Coastal Flood Modeling Issues in Delaware

Jesse Hayden, P.E., DNREC
Michael Powell, DNREC

Difference between types of flood modeling

- Riverine
- Coastal
- Deterministic
- Probabilistic

Products and applications of flood modeling

- Flood risk mapping
- Design of projects both coastal and non-coastal
- SLOSH and ADCIRC Event forecasting

Limitations in the modeling commonly used in Delaware

- Lack of resources to run models for individual storms
- Lack of data
- Models often are not robust enough
- Many forecasting models predict output for the Atlantic Ocean or Delaware Bay (not inland bay or barrier island backside locations)

Coastal management challenges created by insufficient modelling

- Impacts from forecasted events on specific locations very difficult to predict
- Dunes and beaches change seasonally or due to events – risk changes constantly
- Storm parameters which influence impacts complex (storm duration, wind direction, wave heights, wave period, wave direction, inland propagation of surge through inlets and rivermouths, astronomical tide influence, Dune topography,

Where are improvements most needed?

National Storm Surge Hazard Maps

How this map was created:

The SLOSH (Sea, Lake, and Overland Surges from Hurricanes) model is a numerical model used by NWS to compute storm surge. Storm surge is defined as the abnormal rise of water generated by a storm, over and above the predicted astronomical tides. Flooding from storm surge depends on many factors, such as the track, intensity, size, and forward speed of the hurricane and the characteristics of the coastline where it comes ashore or passes nearby. For planning purposes, the NHC uses a representative sample of hypothetical storms to estimate the near worst-case scenario of flooding for each hurricane category.

LEGEND

Category 2 (SLOSH MOMs) Storm Surge Inundation

Inundation Height

- Up to 3 feet above ground
- Greater than 3 feet above ground
- Greater than 6 feet above ground
- Greater than 9 feet above ground

SLOSH grid in Delaware

- 1.5 km² elements at Cape Henlopen
- 1.7 km² elements at Fenwick Island

ADCIRC Predicts Floods

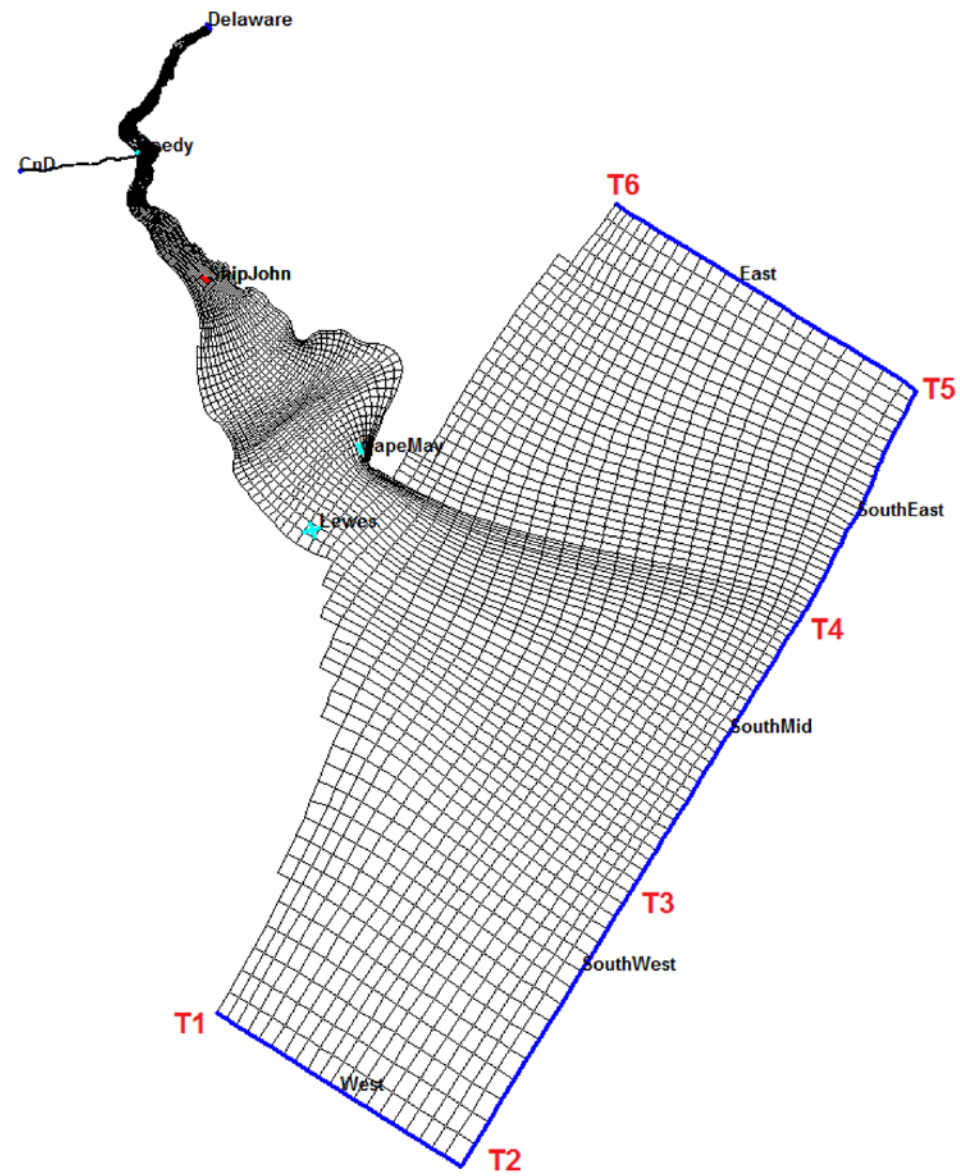

The **ADvanced CIRCulation (ADCIRC) storm surge model*** combines rain, atmospheric pressure, and wind forecasts to predict when, where, and to what extent flooding will inundate a coastal community with greater precision than other available models. This enables decision-makers to identify which locations to evacuate as a storm approaches and to plan for mitigation and response before severe storms occur.

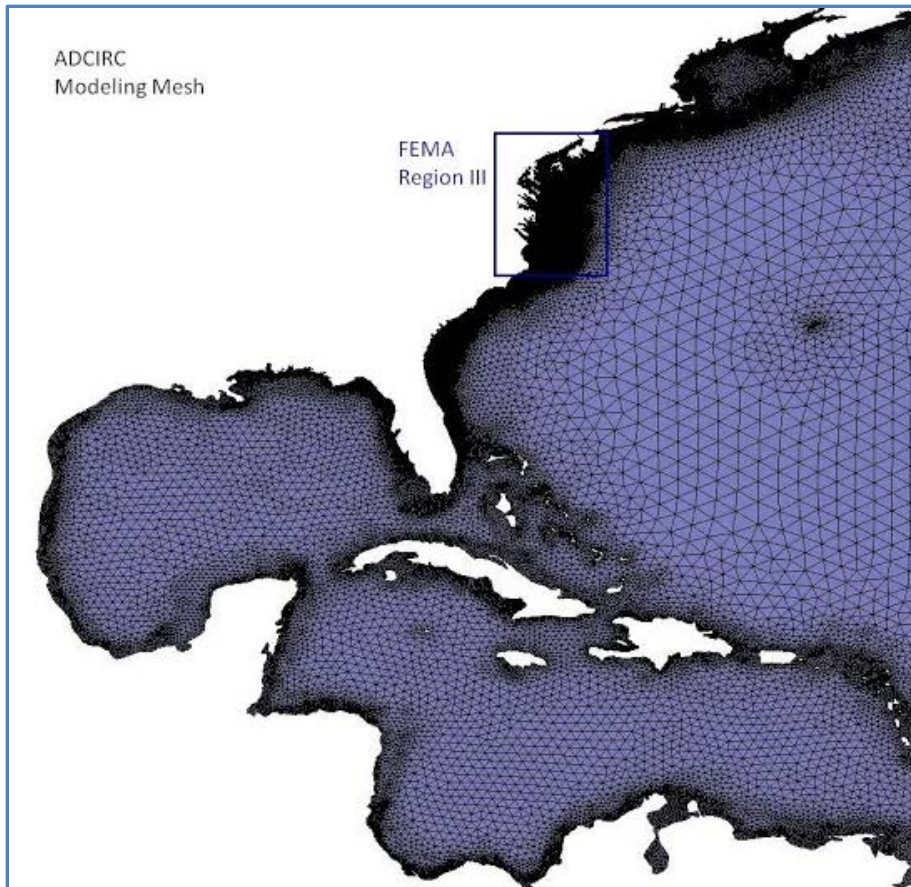

Maximum Water Inundation Forecast, Hurricane Sandy, Oct. 22, 2012, 8:00pm EDT

The ADCIRC Model is Used to:

- Inform nearshore marine operations
- Predict hurricane storm surge and flooding
- Model oil spill movement in nearshore areas
- Model tides and wind-driven water circulation
- Model the impact of potential sea level rise on coastal communities

ADCIRC grid – FEMA modeling

- Unstructured mesh
- Refined near area of interest and around areas of changing topobathy

ADCIRC grid – FEMA modeling

- Nominal 50-100m minimum resolution
- Static topobathy
- No validation in Delaware Inland Bays

Figure 2.11 ADCIRC mesh element resolution in meters in the northern portion of the FEMA Region III domain. Brown lines denote mesh boundaries.

Effect of underlying modelling assumptions:

Effective 2005 FEMA maps assumed significant dune breaching in 100 and 500 year event

Newer studies assume no topographical changes to the barrier islands

2013 Preliminary Still Water Elevations

10 yr SWEL= 3.9 NAVD88

50 yr SWEL= 4.7 NAVD88

100yrSWEL= 4.9 NAVD88

500yrSWEL= 5.8 NAVD88

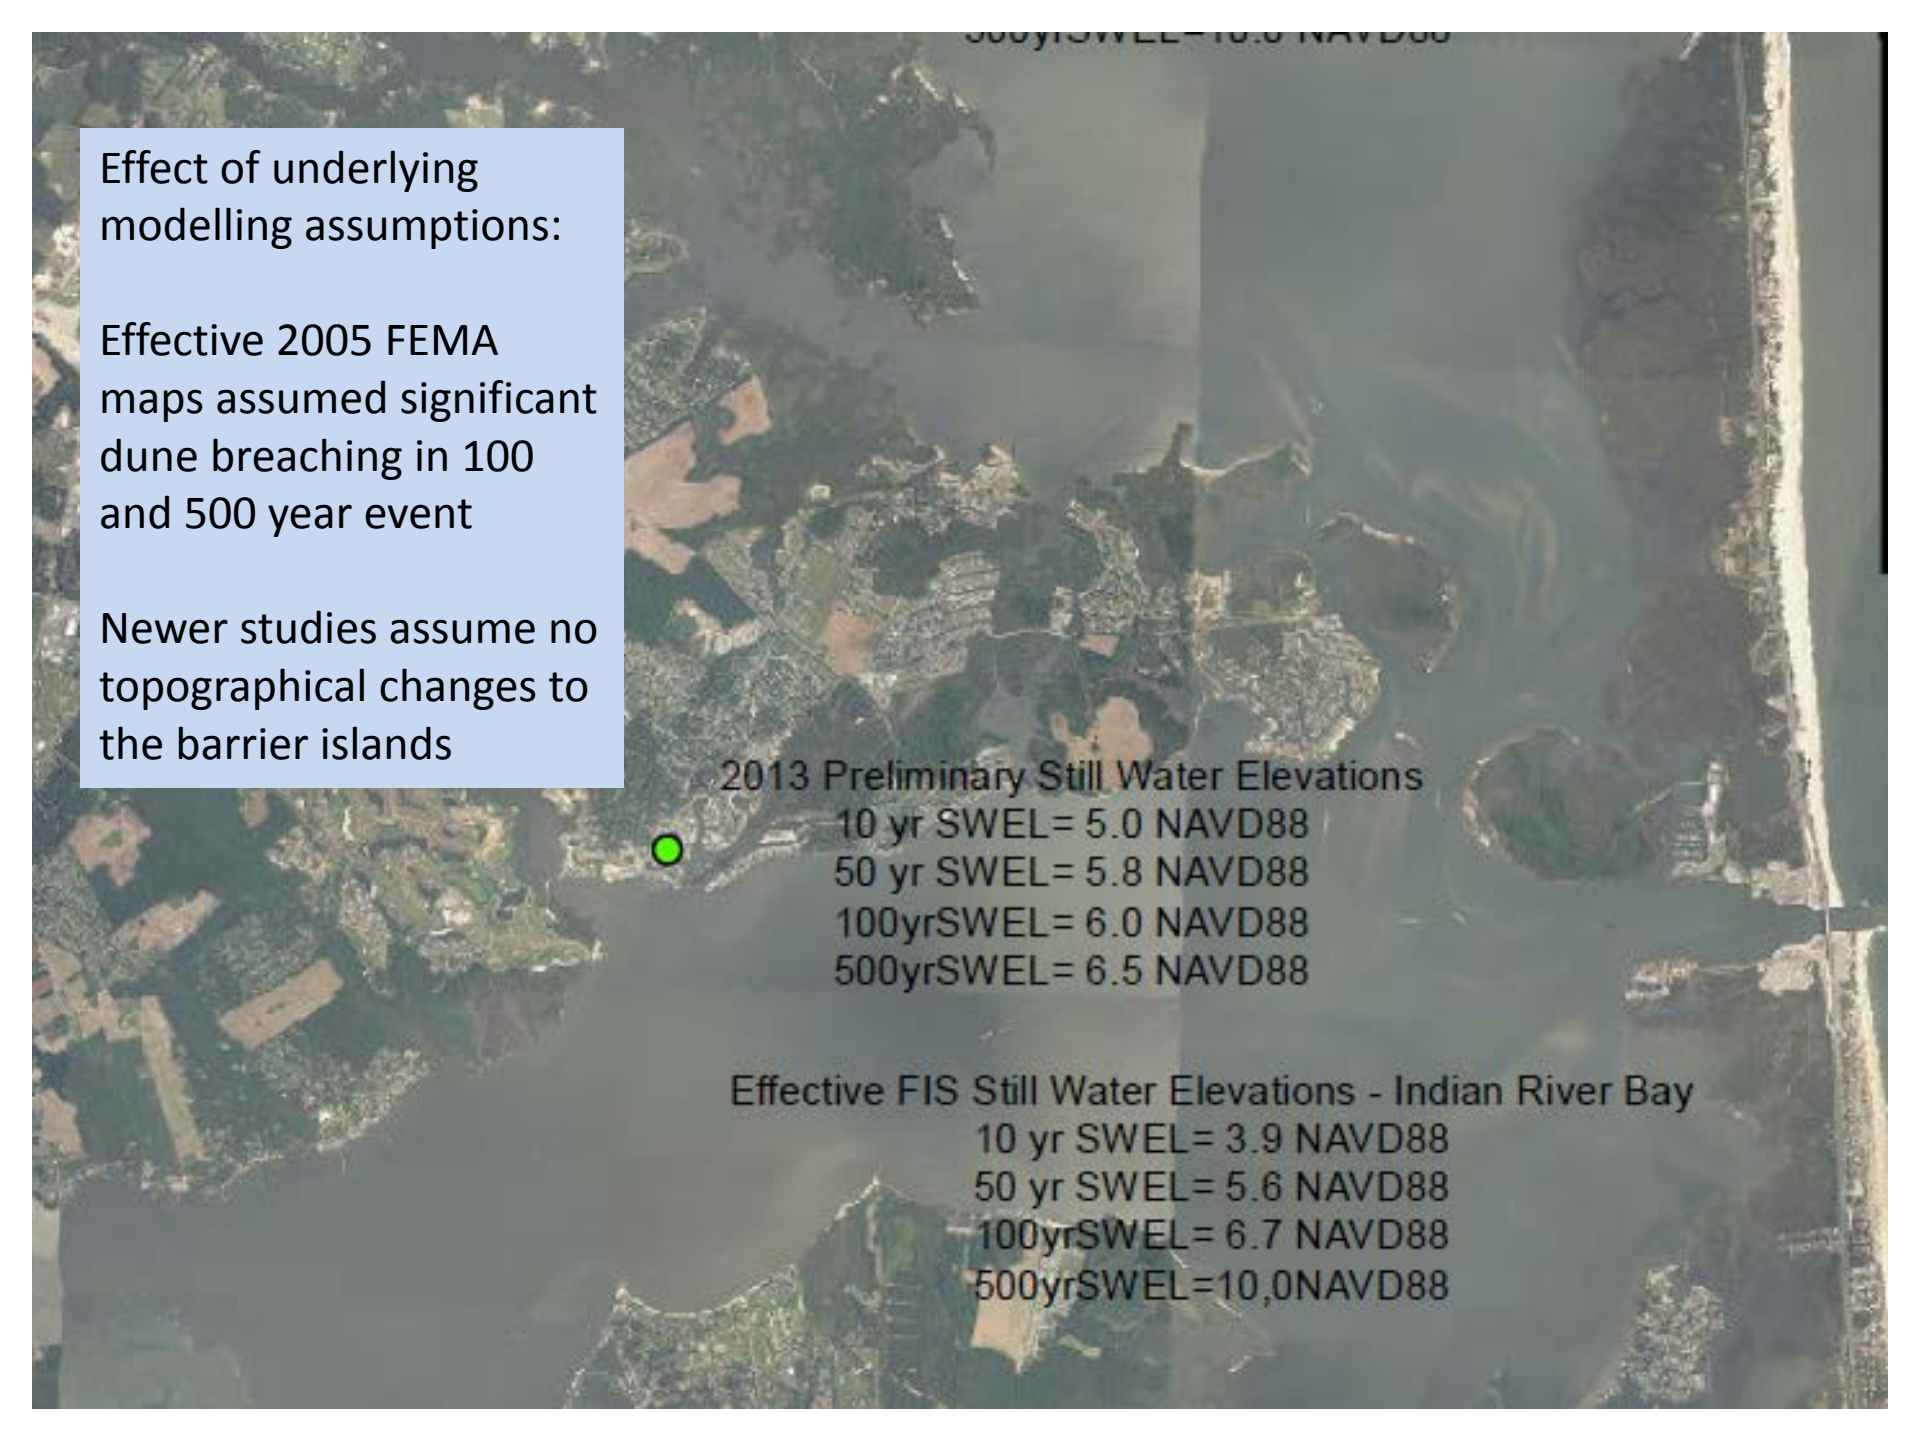

Effective FIS Still Water Elevations - Rehoboth Bay

10 yr SWEL= 3.1 NAVD88

50 yr SWEL= 5.1 NAVD88

100yrSWEL= 6.2 NAVD88

500yrSWEL=10.0 NAVD88

Effect of underlying
modelling assumptions:
